# Defining (Creating) a Function

# Table of Contents

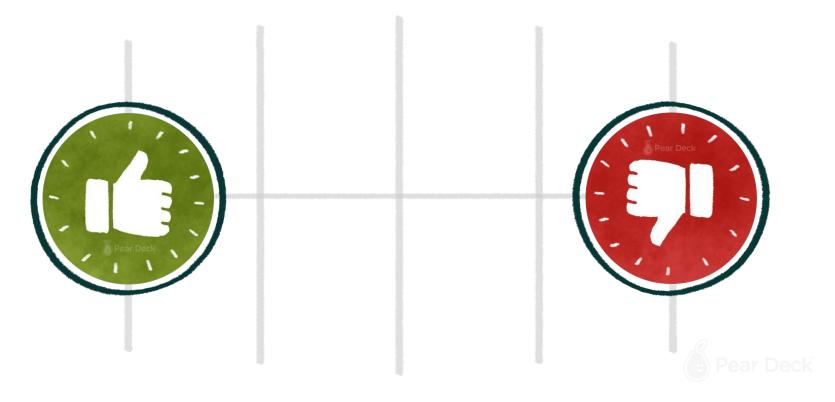

- Main Principles of 'Defining'
- Execution of a Function

## How was the pre-class content?

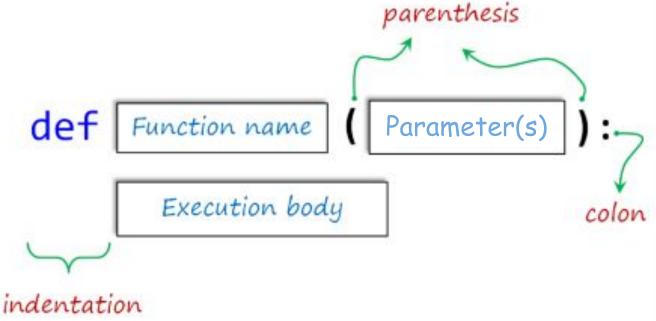

► The basic **formula syntax** of user-defined function is:

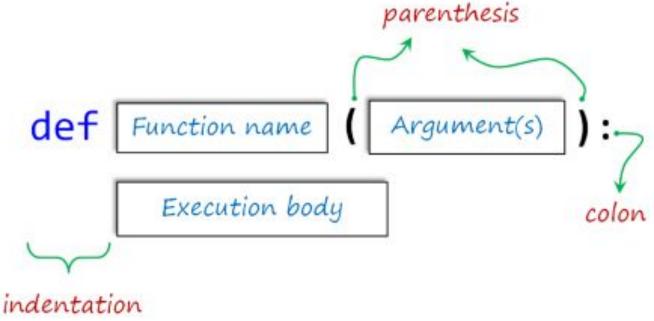

► The basic **formula syntax** of user-defined function is:

Defining a simple function

```
def first_function(parameter_1, parameter_2) :
    print(parameter_1 ** 2 + parameter_2 ** 2)
```

- Let's call and use **first\_function**.
  - first\_function(2, 3) # here, the values (2 and 3) are
     allocated to the arguments

- Let's call and use first\_function.
- first\_function(2, 3) # here, the values (2 and 3) are
   allocated to the arguments
  - 1 13

Let's define the multiplying function multiply(a, b).

```
def multiply(a, b):
    print(a * b)

multiply(3, 5)
multiply(-1, 2.5)
multiply('amazing ', 3) # it's really amazing, right?
```

What is the output? Try to figure out in your mind...

Let's define the multiplying function multiply(a, b).

```
def multiply(a, b):
    print(a * b)

multiply(3, 5)
multiply(-1, 2.5)
multiply('amazing ', 3) # it's really amazing, right?
```

```
1 15
2 -2.5
3 amazing amazing
```

Let's give an example by leaving the parentheses empty.

```
def motto():
    print("Don't hesitate to reinvent yourself!")
    motto() # it takes no argument
```

What is the output? Try to figure out in your mind...

Let's give an example by leaving the parentheses empty.

```
def motto():
    print("Don't hesitate to reinvent yourself!")
    motto() # it takes no argument
```

1 Don't hesitate to reinvent yourself!

#### Task:

Define a function named add to sum two numbers and print the result.

#### The code can be like:

```
1 v def add(a, b):
2     print(a + b)
3     4     add(-3, 5)
5
```

## Output

2

#### Task:

- Define a function named calculator to calculate four math operations with two numbers and print the result.
- Warn user in case of wrong entry: "Enter valid arguments"

```
1 calculator(88, 22, "+")
3 Output
```

110

### The code might be like:

```
1 √ def calculator(x, y, opr):
        if opr == "+" :
            print(x + y)
        elif opr == "-" :
4 ▼
            print(x - y)
6 ▼
        elif opr == "*" :
            print(x * y)
8 *
        elif opr == "/" :
            print(x / y)
10 🔻
        else:
11
            print("enter valid arguments!")
```

## 2 Execution of a Function

```
    print
    return
    multiply_1(a, b):
    print(a * b) # it prints something
    multiply_1(10, 5)
```

## Execution of a Function (review)

```
    print
        return(a * b) # returns any numeric
        data type value
        print(multiply_2(10, 5))
```

## Execution of a Function (review)

```
oprint
return(a * b) # returns any numeric
data type value
print(multiply_2(10, 5))
```

Compare the usage options:

```
print(type(multiply_1(10, 5)))
print(type(multiply_2(10, 5)))
```

The outputs are :

```
1 print(type(multiply_1(10, 5)))
2 print(type(multiply_2(10, 5)))

1 50
2 <class 'NoneType'>
3 <class 'int'>
```

#### Task:

Define a function named calculator to calculate four math operations with two numbers and return the result.

```
print(calculator(-12, 2, "+"))

Output
```

-10

The code might be like:

```
1 def calculator(x, y, o):
        if o == "+" :
            return(x + y)
        elif o == "-" :
            return(x - y)
        elif o == "*" :
            return(x * y)
8 *
        elif o == "/" :
            return(x / y)
        else : return ("enter valid arguments!")
10
11
```

#### Task:

- Define a function named absolute\_value to calculate and return absolute value of the entered number.
- You can add docstring for an explanation.

```
print(absolute_value(3.3))
print(absolute_value(-4))
```

## Output

```
3.3
4
```

The code might be like:

```
def absolute value(num):
          """This function returns the absolute
          value of the entered number"
   4
   5 ₹
          if num >= 0:
   6
                                                 By the way, we can
               return num
                                                display the docstring
          else:
                                                   of this function
               return -num
      print(absolute value. doc 
  10
Output
  This function returns the absolute
      value of the entered number
```
